                                183
                                              64
                                                                0 23.3
                                                                            0.672
                                                                                    32
                                                                                                  1
                                                        23
                                                                   28.1
                                                                            0.167
                     1
                                 89
                                              66
                                                               94
                                                                                    21
                                                                            2.288
                     0
                                137
                                              40
                                                        35
                                                              168 43.1
                                                                                    33
In [3]: len(df)
Out[3]: 768
```

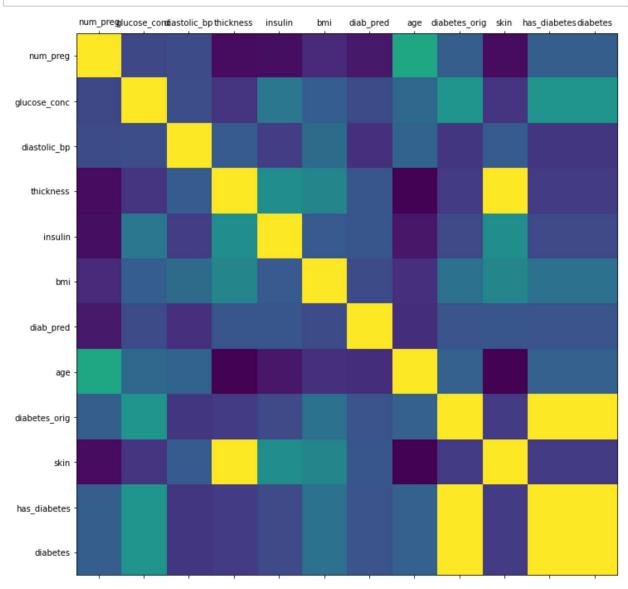

step 2 : clean data

2.a - let us find if there are any null values

```
In [4]: df.isnull().values.any()
Out[4]: False
```

2.b - let us find duplicate columns or co-related columns

```
In [7]: #lets call above function
plot_corr(df)
```

```
In [8]: # we are going to remove thickness, diabetes_orig,has_diabetes
In [9]: del df['thickness']
del df['has_diabetes']
```

del df['diabetes_orig']

```
In [10]: df.head()
```

Out[10]:

	num_preg	glucose_conc	diastolic_bp	insulin	bmi	diab_pred	age	skin	diabetes
0	6	148	72	0	33.6	0.627	50	1.3790	True
1	1	85	66	0	26.6	0.351	31	1.1426	False
2	8	183	64	0	23.3	0.672	32	0.0000	True
3	1	89	66	94	28.1	0.167	21	0.9062	False
4	0	137	40	168	43.1	2.288	33	1.3790	True

2.c - lets convert text to numbers

0

machine learning algorithms will not understand text. so convert to numbers.

```
In [11]: diabetes_map = {True:1, False:0}
          df['diabetes'] = df['diabetes'].map(diabetes map)
In [12]: df.head()
Out[12]:
              num_preg

                                               66
                                                      94
                                                         28.1
                                                                   0.167
                                                                          21
                                                                              0.9062
```

let us check proportion of diabetes vs non-diabetes data

40

168 43.1

137

we need to ensure that the proportion should be balanced (50-50) diabetes and non diabetes or at least close enough to proceed.

2.288

33 1.3790

1

in case of data imbalance we use SMOTE technique to increase lesser data samples.

step 3 - train test split

let us split our data for training and testing the algorithm

```
In [14]: | from sklearn.model_selection import train_test_split
         feature_col_names = ['num_preg','glucose_conc', 'diastolic_bp',
                               'insulin','bmi','diab_pred','age','skin']
         predicted_class_names = ['diabetes']
         x = df[feature_col_names].values
         y = df[predicted_class_names].values
         split_test_size = 0.30
         x_train, x_test, y_train, y_test = train_test_split(x,y,
                                         test_size=split_test_size, random_state=42)
In [15]: | print('# rows in dataframe {0}'.format(len(df)))
         print('# rows missing glucose_conc : {0}'.format(len(df.loc[df['glucose_conc']==
         print('# rows missing diastolic bp : {0}'.format(len(df.loc[df['diastolic bp']==
         print('# rows missing thickness : {0}'.format(len(df.loc[df['skin']== 0])))
         print('# rows missing insulin : {0}'.format(len(df.loc[df['insulin']== 0])))
         print('# rows missing bmi : {0}'.format(len(df.loc[df['bmi']== 0])))
         print('# rows missing diab pred : {0}'.format(len(df.loc[df['diab pred']== 0])))
         print('# rows missing age : {0}'.format(len(df.loc[df['age']== 0])))
         # rows in dataframe 768
         # rows missing glucose conc : 5
         # rows missing diastolic bp : 35
         # rows missing thickness : 227
         # rows missing insulin : 374
         # rows missing bmi : 11
         # rows missing diab pred : 0
         # rows missing age : 0
In [16]: # lets fill 0's with valid data (either mean or mode)
In [17]: from sklearn.impute import SimpleImputer
         fill_0 = SimpleImputer(missing_values=0, strategy='mean')
         #fill_0 = Imputer(missing_values=0, strategy='mean', axis=0)
         x train = fill 0.fit transform(x train)
         x test = fill 0.fit transform(x test)
```

```
In [18]: x_train[0:10]
Out[18]: array([[1.00000000e+00, 9.50000000e+01, 6.00000000e+01, 5.80000000e+01,

```

step 4 - TRAIN THE MODEL

step 5 - TESTING MODEL

accuracy : 0.7359

step 6 - ANALYZE THE MODEL ACCURACY

WITH THE HELP OF "CONFUSION MATRIX" WE CAN ANALYZE ALGORITHMS PERFORMANCE

```
print('confusion matrix')
In [23]:
         print('{0}'.format(metrics.confusion_matrix(y_test, nb_predict_test)))
         print('')
         print('classification report')
         print(metrics.classification_report(y_test, nb_predict_test))
         confusion matrix
         [[118 33]
          [ 28 52]]
         classification report
                       precision recall f1-score
                                                       support
                    0
                            0.81

         on)
```

final conclusion - we are suggesting random forest algorithm for this project as the accuracy is 75% and recall value is 82% which is higher than other 2 algorithms (i.e naive byes and logistic regression aglorithm)
